FAST NUCES CFD

Objectives

- Moore Machines
- Mealy Machines
- Moore = Mealy

Benefits

- What if we want to do following to the word
 - count the occurrence of a certain substring
 - get the incremented number
 - mark the locations of the substring in the word
 - take the complement of the number
 - Get the parity of the number
-
- Final accepted/rejected may not be required
 - Not limited by the size of the buffer if we want to wait for the final output

Moore vs Mealy Machine

Moore Machine

Moore machine is a collection of five things:

1. **A finite set of states $q_0, q_1, q_2, \dots$** , where q_0 is designated as the start state.
2. An alphabet of letters for forming the **input string** = **$\{a, b, c, \dots\}$** .
3. An alphabet of possible output **characters** **$\Gamma = \{0, 1, 2, \dots\}$** .
4. A transition table that shows for **each state and each input letter what state is reached next**.
5. An output table that shows what **character from Γ** is printed by each state as it is entered.

Moore Machine

- We did not assume that the input alphabet is the same as the output alphabet Γ .
- To keep the output alphabet separate from the input alphabet, we give it a different name Γ (instead of Σ) and use number symbols $\{0, 1, \dots\}$ (instead of $\{a, b, \dots\}$).
- We refer to input symbols as letters, whereas we refer to output symbols as characters.
- We adopt the policy that a Moore machine always begins by printing the character dictated by the mandatory start state. So, if the input string has 7 letters, then the output string will have 8 characters, because it includes 8 states in its path.

- A Moore machine does not define a language of accepted words, because there is no such thing as a final state.
- Every possible input string creates an output string. The processing is terminated when the last input letter is read and the last output character is printed.
- There are some subtle ways to turn Moore machines into language definers.

Moore machine defined by a table

- Input alphabet: $\Sigma = \{a, b\}$
- Output alphabet: $\Gamma = \{0, 1\}$
- Names of states: q_0, q_1, q_2, q_3 with q_0 being the start state.
- Transition and output table (combined):

Old State	Output by Old State	New state after a	New state after b
q_0	1	q_1	q_3
q_1	0	q_3	q_1
q_2	0	q_0	q_3
q_3	1	q_1	q_2

Moore machine defined by a table

Old State	Output by Old State	New state after a	New state after b
q_0	1	q_1	q_3
q_1	0	q_3	q_1
q_2	0	q_0	q_3
q_3	1	q_1	q_2

Pictorial Representation

- Moore machines have pictorial representations similar to FAs.
- The difference is that inside each state, in addition to the state name, we also specify the output character printed by that state, using the format state – name/output.
- Hence, the Moore machine in the above example has the following pictorial representation:

Example

Old State	Output by Old State	New state after a	New state after b
q_0	1	q_1	q_3
q_1	0	q_3	q_1
q_2	0	q_0	q_3
q_3	1	q_1	q_2

- We indicate the start state by an outside arrow since there is no room for the usual - sign.
- Given the input string $abab$, the output sequence is 10010.
- Note that the length of the output string is one longer than the length of the input string.

Example

Mealy Machine

- A Mealy machine is a collection of four things:
- A finite set of states $q_0, q_1, q_2, \dots$, where q_0 is designated as the start state.
- An alphabet of letters for forming the input string $\Sigma = \{a, b, \dots\}$.
- An alphabet of possible output characters $\Gamma = \{0, 1, \dots\}$.
- A pictorial representation with states represented by small circles and directed edges indicating transition between states.

Mealy Machine

- Each edge is labeled with a compound **symbol of the form i/o** where i is an input letter and o is an output character.
- Every state must have **exactly one outgoing edge for each possible input letter.**
- The edge we travel is determined by the input letter i . While traveling on the edge, we must print the output character o .

Example

State	Input a	Output (input a)	Input b	Output (input b)
q0	q1	0	q3	0
q1	q3	1	q2	1
q2	q3	0	q3	1
q3	q3	1	q0	1

- A Mealy machine does not define a language by accepting and rejecting input strings: It has no final states.
- However, there is a sense in which a **Mealy machine can recognize a language**, as we will see later.
- Note the following notation simplification:

Example:

- The following Mealy machine prints out the 1's complement of an input bit string.
- This means that it will produce a bit string that has a 1 whenever the input string has a 0, and a 0 whenever the input has a 1.

- If the input string is 001010, the output will be 110101

Example 1

- Let consider a Mealy machine, **called increment machine**, which reads a binary number and prints out the binary number that is one larger.
- Assume that the input bit string is a binary number fed in backward; that is, unit **digit first, then 2's digit, 4's digit, etc.**
- The output string will be the binary number that is one greater and that is generated right to left.
- The machine will have 3 states: start, owe-carry and no-carry. The owe-carry state represents the overflow when two bits of 1's are added, we print a 0 and we carry a 1.

Example 1

- From the start state, if we read a 0, we print a 1 (incrementing process), and we go to the no-carry state. If we read a 1, we print a 0 (incrementing) and we go to the owe-carry state.
- At any point in the process, in we are in the no-carry state, we print the next bit just as we read it and remains in no-carry.
- However, if we are in the owe-carry state and read a 0, we print a 1 and go to no-carry. If we are in owe-carry and read a 1, we print a 0 and we loop back to owe-carry.

Example 1

- Let the input string be 1011 (binary representation of 11).
- The string is fed into the machine as 1101 (backwards).
- The output will be 0011, which when reversed is 1100 and is the binary representation of 12.
- In Mealy machine, output length = input length. Hence, if input were 1111, then output would be 0000 (**overflow situation**).

Moore = Mealy

- So far, we have define that two machines are equivalent if they accept the same language.
- In this sense, we cannot compare a Mealy machine and a Moore machine because they are not language definers.

Definition:

- Given the Mealy machine Me and the Moore machine Mo (which prints the automatic start state character x), we say that these two machines are **equivalent** if for every input string, the output string from Mo is exactly x concatenated with the output string from Me .

Theorem

If M_o is a Moore machine, then there is a Mealy machine M_e that is equivalent to M_o .

Proof by constructive algorithm:

- Consider a particular state in M_o , say state q_4 , which prints a certain character, say t .
- Consider all the incoming edges to q_4 . Suppose these edges are labeled with $a, b, c, \dots$
- Let us re-label these edges as $a/t, b/t, c/t, \dots$ and let us erase the t from inside the state q_4 . This means that we shall be printing a t on the incoming edges before we enter q_4 .

Proof by constructive algorithm contd.

- We leave the outgoing edges from q_4 alone. They will be relabeled to print the character associated with the state to which they lead.
- If we repeat this procedure for every state $q_0, q_1, \dots$, we turn M_0 into its equivalent M_e .

Example

- Following the above algorithm, we convert a Moore machine into a Mealy machine as follows:

Theorem

For every Mealy machine M_e , there is a Moore machine M_o that is equivalent to it.

Proof by constructive algorithm:

- We cannot just do the reverse of the previous algorithm. If we try to push the printing instruction from the edge (as it is in M_e) to the inside of the state (as it should be for M_o), we may end up with a conflict: Two edges may come into the same state but have different printing instructions, as in this example:

- What we need are two copies of q_4 , one that prints a 0 (labeled as $q_4^1/0$), and the other that prints a 1 (labeled as $q_4^2/1$). Hence,

- The edges $a/0$ and $b/0$ will go into $q_4^1/0$.
- The edge $b/1$ will go into $q_4^2/1$.

- The arrow coming out of each of these two copies must be the same as the edges coming out of q_4 originally.

Proof by constructive algorithm (cont.):

- If there is ever a state that has no incoming edges, we can assign it any printing instruction we want, even if this state is the start state.
- *If we have to make copies of the start state in Me , we can let any of the copies be the start state in Mo , because they all give the identical directions for proceeding to other states.*
- Having a choice of start states means that the conversion of Me into Mo is NOT unique.
- Repeating this process for each state of Me will produce an equivalent Mo . The proof is completed.
- **Together, Theorems 8 and 9 allow us to say $Me = Mo$.**

Example

- Convert the following Mealy machine into a Moore machine:

Step 1:

Step 2:

- All the edges coming into state q_1 (and also q_3) have the same printing instruction. So, apply the algorithm to q_2 and q_3 :

Step 3:

- The only job left is to convert state q_2 . There are 0-printing edges and 1-printing edges coming into q_2 . So, we need two copies of q_2 . The final Moore machine is:
